1. Part I

2. Introduction

The aim of this paper is to replicate the work by MacDonald & Ricci (2004). They analyse the determinants of the Real Effective Exchange Rate (REER) based on a collection of variables as determinants, using a Vector Error Correction Model. The purpose of their study was to use the most current research to investigate a set of variables with explanatory power in determining the long term behaviour of the REER in South Africa. They used the period starting from the first quarter of 1970 until the first quarter of the year 2002. Towards this end, they made use of the Maximum Likelihood method of estimating the VECM, developed in Johansen (1995). Their choice of variables is based on the most recent research at the time, of the determinants of the real exchange rate in developing economies such as South Africa. This paper serves to replicate the steps taken by MacDonald & Ricci (2004) and reach a conclusion independently, and thus will critically evaluate the logical flow towards estimating the final model. Therefore, additional tests and evaluations are made to reassess the robustness of the final mode.

The choice of the model vector introduced later, is based on several developments prior to 2004. Briefly, the variables have been found to serve as feasible explanatory variables for the REER includes: productivity, real interest rates relative to mostly traded with, the relative openness of the selected economy to trade, and the magnitude of the fiscal balance and net foreign assets (MacDonald & Ricci, 2004).

The Purchasing Power Parity (PPP) points to the equality between the price levels between two countries if they were quoted in the same currencies. When the PPP holds, the real exchange rate must not vary (Sarno & Taylor, 2002). The VECM for the REER is thus an attempt to elucidate the nature of deviations from the PPP. A comprehensive and accurate model for the deviations from the PPP that is explainable by real factors would provide an appropriate framework for policy-makers to respond with ideal policy (Sarno & Taylor, 2002). In light of this, MacDonald & Ricci (2004) attempt to bring various explanatory variables together in a broad model that can appropriately explain these deviations.

Part II: Replication

3. Importing and Cleaning the Data

4. Plotting the Model Variables (STEP 0.)

Figures 4.1 & 4.2 displays each variable as they as they were before their natural logarithm transformation.

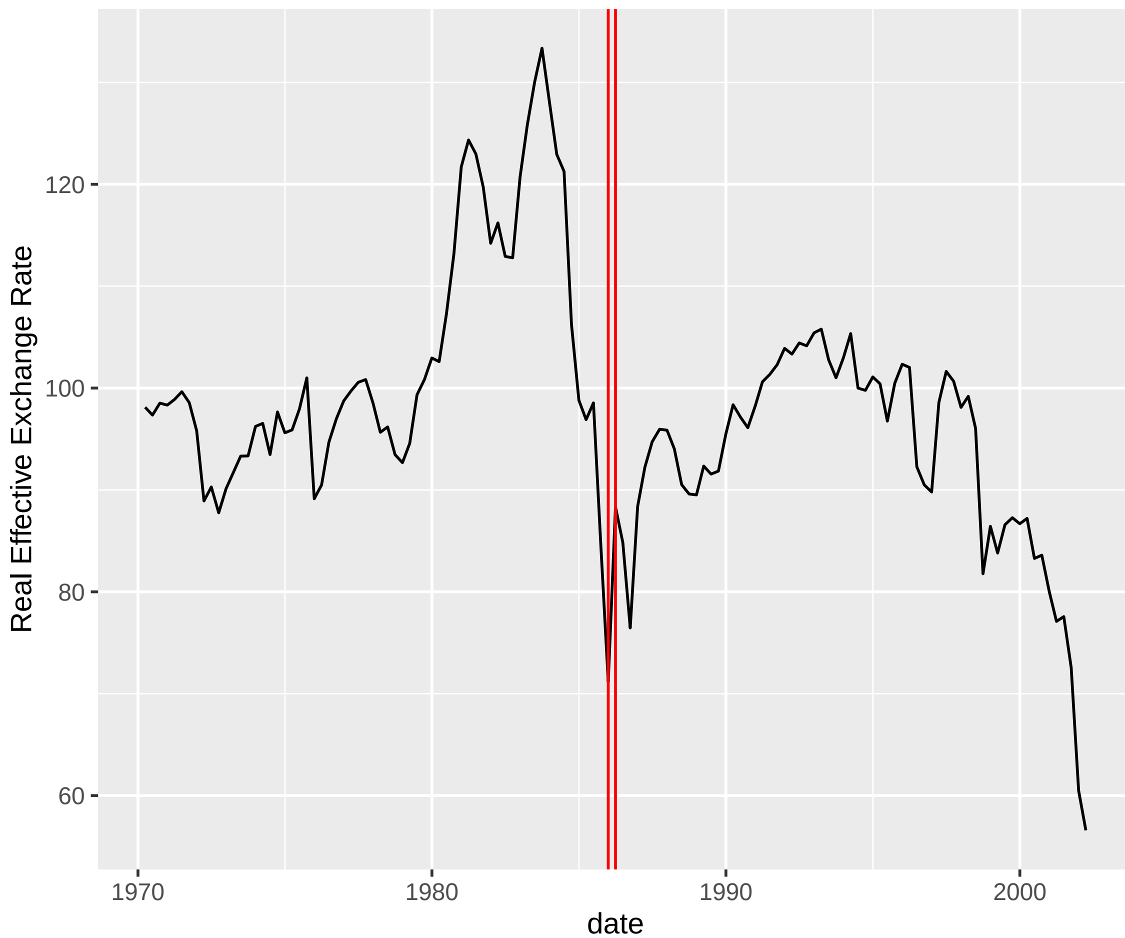

Figure 4.1: The South Africa Real Exchange Rate

might have to rethink this: The regime changes might be accounted for/proxied by including the openness, real commodity prices and net foreign assets??

The red lines indicate the dates at which dummy variables for possible outliers will be included as an alternative model specification. This alternative specification aims to account for the large changes in the real exchange rate regime over the period. There was little consistency in the manner in which the real exchange rate was determined over the period from 1970 to 2002. Most significantly, intermittent changes in the degree and nature of intervention from the South African Reserve Bank (SARB) suggests that the explanatory factors determining the REER will necessary be inconsistent over this period (Aron, Elbadawi & Kahn, 1998). The period from 1979 to 1988 from figure 4.1 for example, is visually unique from the rest of the time series. The coincidence seems unlikely with some research suggesting that intervention during this period was based on maintaining the real price of gold in rand (Aron *et al.*, 1998). This suggests that a model that can account for some structural deviations might be more appropriate. The VECM developed by MacDonald & Ricci (2004) to explain the equilibrium deviations of the REER might achieve more preciseness by accounting for these periods of deviation from free market behaviour.

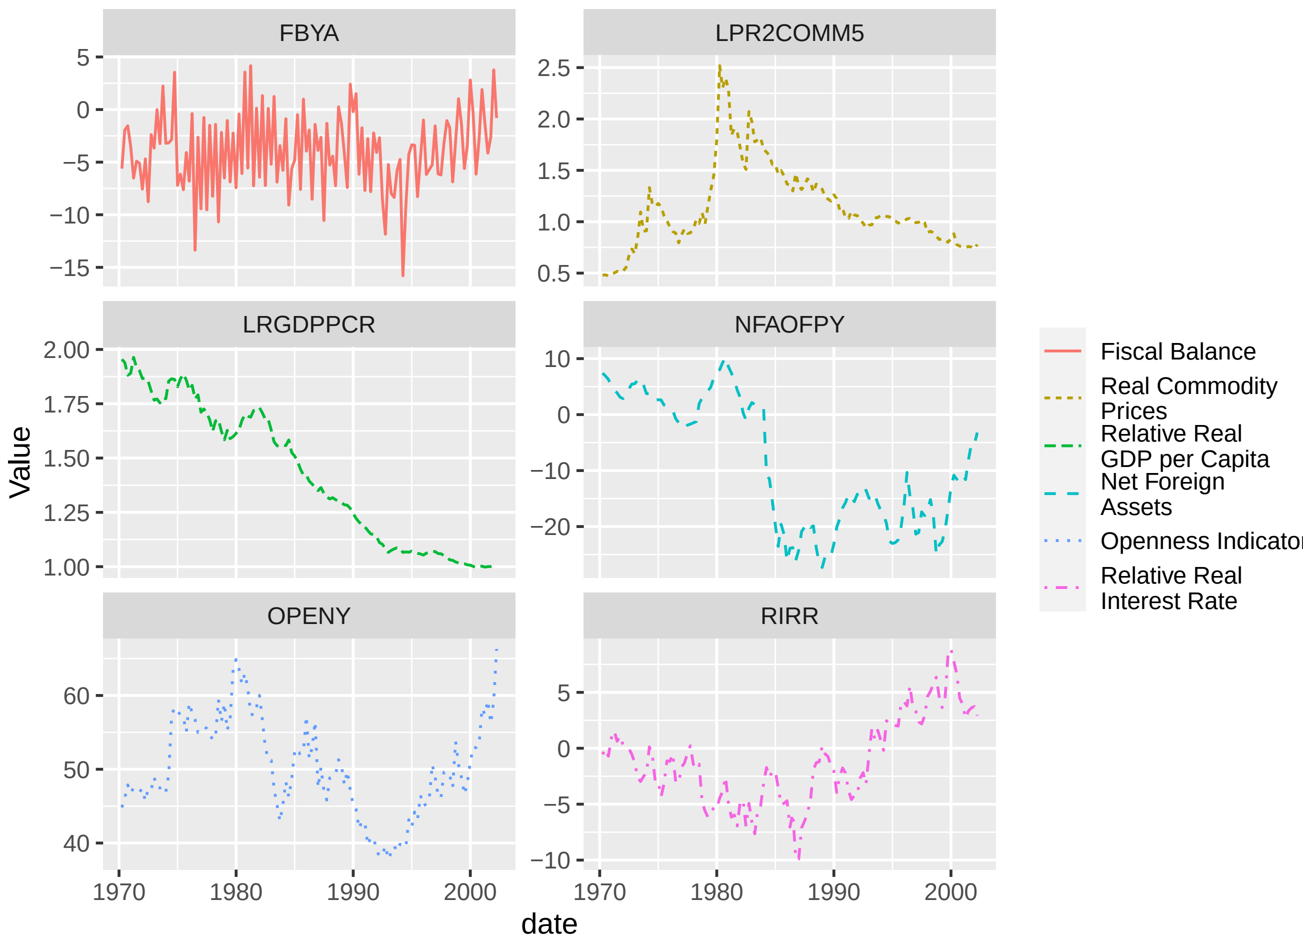

Figure 4.2: Determinants of the Real Exchange Rate for South Africa

Figure 4.2 above might also suggest that there is a possible structural break in the time series around the year 1985. This is mostly evident in the behaviour of the variable `NFAOFPY`, the Net Foreign Assets proxy. The openness indicator, Relative Real Interest Rate, Relative Real GDP, and Real Commodity prices slightly correspond to this theory as well. A test for this is therefore necessary.

To illustrate the co-movement of the system, figure **??** below plots them jointly. Note that the Openness Indicator has also been logged to make the visual comparison easier.

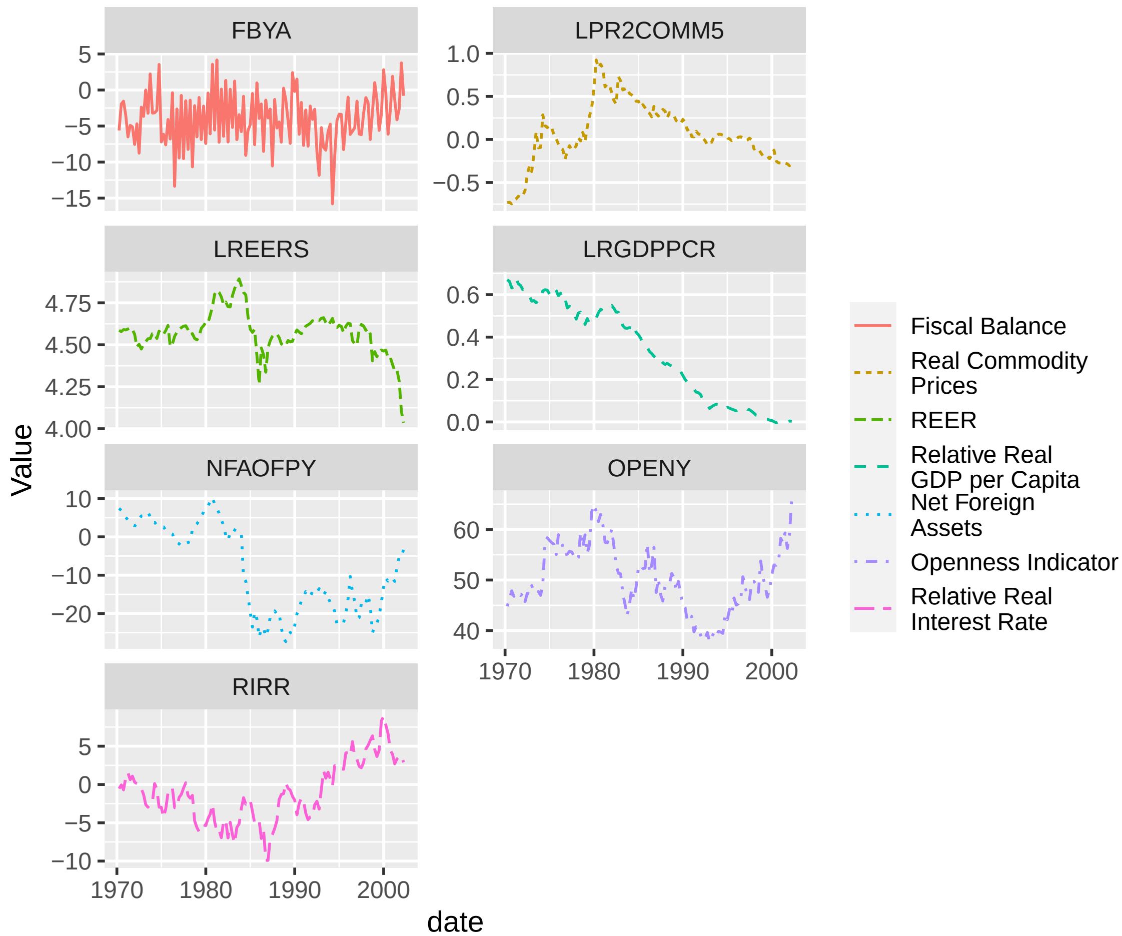

Figure 4.3: The Joint plot of the Model Varibales (Logged where necessary)

A relative degree of co-movement is noticeable in each of these time series altogether. The Log of Real GDP, however, requires one to take into account the declining trend, after which the co-movement seems more evident. Also worth noting, is that none of these series seem to be stationary.

5. The Johansen Method in Theory

explain johansen method

The Johansen (1995) method requires six steps in the estimation process, which follows as:

1. Choosing a specification for the deterministic parts of the model
2. Pre-testing the variables in the system to ensure that they are likely integrated of order one (i.e. $x_t \sim I(1)$\$)
3. Estimating the unrestricted Vector Autoregressive model in levels and checking this models adequacy
4. Estimating the VECM form and determining the cointegration rank (i.e. ‘r’)
5. etc.

6. 0. Plotting the Diffirenced Variables (STEP 1.)

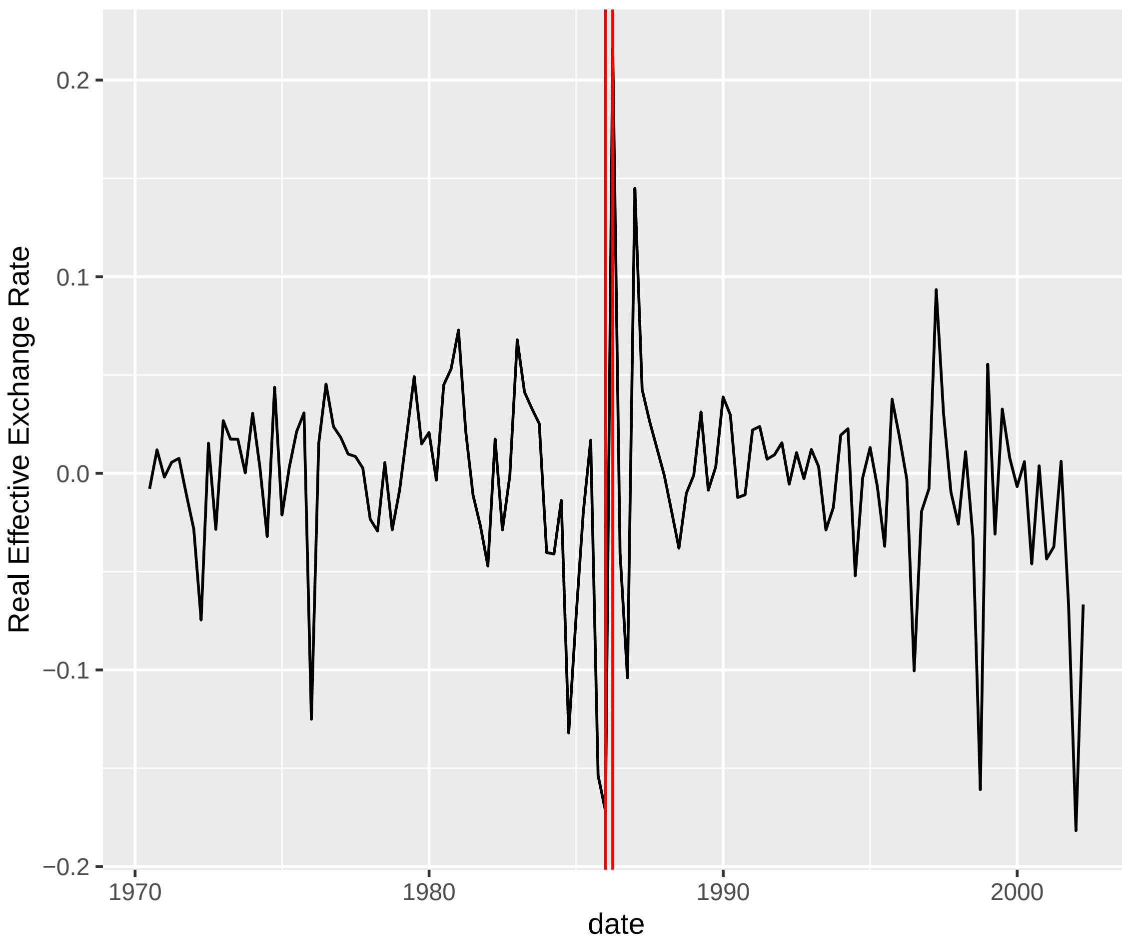

Figure 6.1: The First Difference of the LREERS

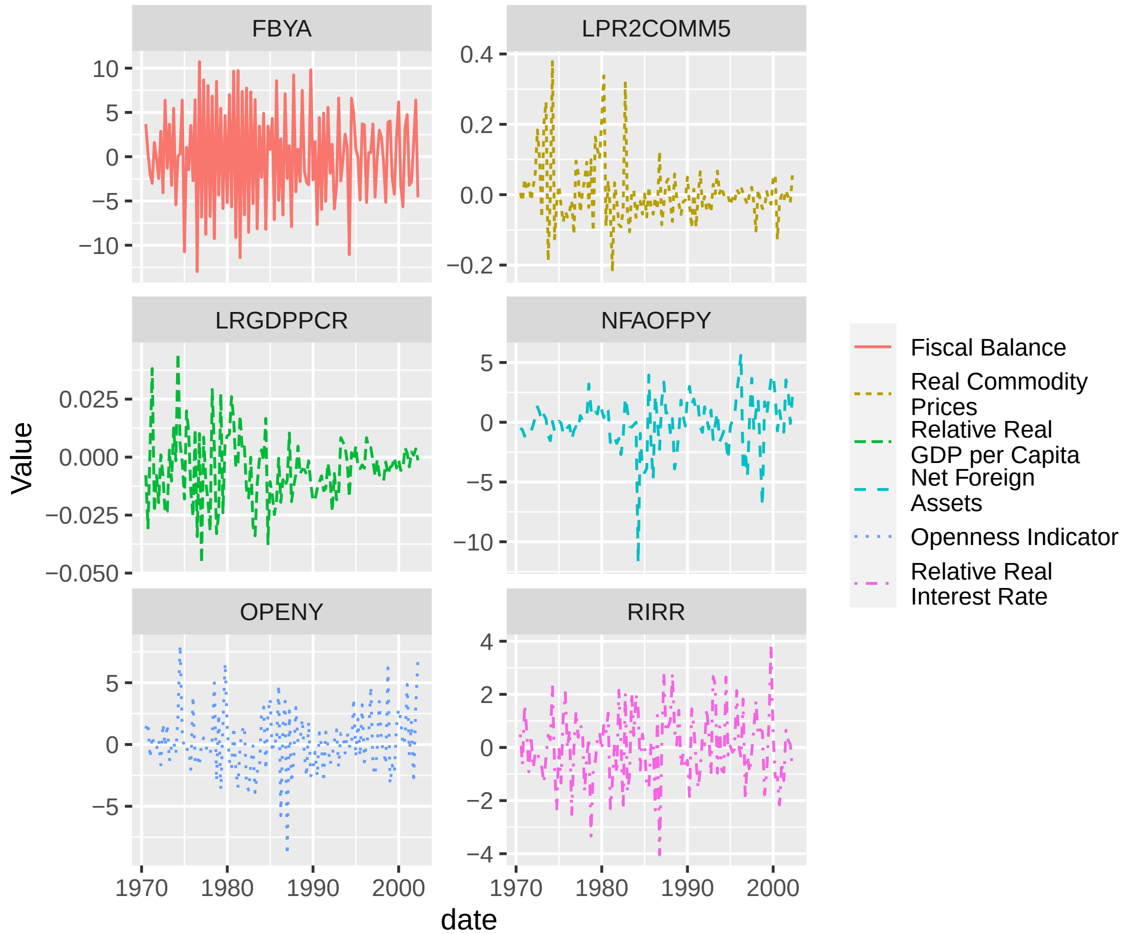

Figure 6.2: The First Difference of the Determinants of the Real Exchange Rate

figures 6.2 and 6.1 above suggest that the REER time series and its candidate explanatory variables are possibly integrated of the first order (i.e. $REER \sim I(1)$). The deterministic component is most likely a constant term. Each of these variables seem somewhat stationary after their first difference is been determined.

```

To test this hypothesis, that each of these series are only stationary after the first difference, the Augmented Dickey Fuller test is employed. The Augmented Dicky-Fuller tests for the differenced time series values of all the variables in the system, as well as the first difference of each of these series are displayed in figures **??** and **??** above. The figures confirm that none of the variables are stationary, and that all but `NFAOFPY` i.e. the net foreign assets are stationary after the first difference. For those that are stationary, the null hypothesis was rejected at the 1% significance level, barring the openness indicator for which the p-value is less than 0.05. This might be due to the large deviations created by the apartheid era sanctions (MacDonald & Ricci, 2004).

6.1. VECM Model Estimation in Theory:

paper table 1 col's:

1. Var's + Seasonal(4) + lags(4) 2. ^{Above} *+ outlier_dummies -> Trace test* $\implies$ *two CI vectors*

Multiple ways to estimate VEC models:

First approach: ordinary least squares (yields accurate result) but does not allow to estimate the cointegrating relations among the variables. The estimated generalised least squares (EGLS) approach would be an alternative.

Most popular estimator: MLE of Johansen (1995) [In R: ca.jo function of the urca package of Pfaff (2008a)] Alternatively, ***`VECM`*** *of tsDyn package of Di Narzo et al. (2020)*

Before VECM: 1. Determine lag order p -> Det. rank of CI matrix r 2. deterministic terms have to be specified. 3. Choose lag order: est. the VAR in levels 4. Choose lag specification that minimises an Information criterion

7. 1.A: Estimating the Unrestricted VAR in Levels and Checking Adequacy

```
options(scipen=999)
var_aic <- VAR(endog_df[,c(2:8)], type = "const", lag.max = 8,
               ic = "AIC", season = 4)

VARselect(endog_df[,c(2:8)], type = "const", lag.max = 4, season = 4)$selection
```

```
## AIC(n)  HQ(n)  SC(n) FPE(n)
```

```
##      1      1      1      1
```

```
VARselect(endog_df[,c(2:8)], type = "const", lag.max = 4, season = 4,
          exogen = exog_df[,5:8])$selection
```

```
## AIC(n)  HQ(n)  SC(n) FPE(n)
##      1      1      1      1
```

```
var_aic2 <- endog_df %>% dplyr::select(2:8) %>% VAR(., type = "const", season = 4,
                                             exogen = exog_df[,5:8],
                                             lag.max = 8, ic = "AIC")
# var_aic3 <- endog_df %>% dplyr::select(2:7 | 9) %>% VAR(., type = "const", season = 4,
#                                               exogen = exog_df[,5:8],
#                                               lag.max = 8, ic = "AIC")
#
# var_aic4 <- endog_df %>% dplyr::select(2:7 | 10) %>% VAR(., type = "const", season = 4,
#                                               exogen = exog_df[,5:8],
#                                               lag.max = 8, ic = "AIC")
#
# var_aic5 <- endog_df %>% dplyr::select(2:7 | 11) %>% VAR(., type = "const", season = 4,
#                                               exogen = exog_df[,5:8],
#                                               lag.max = 8, ic = "AIC")
#
# var_aic6 <- endog_df %>% dplyr::select(2:7 | 12) %>% VAR(., type = "const", season = 4,
#                                               exogen = exog_df[,5:8],
#                                               lag.max = 8, ic = "AIC")
#
# var_aic7 <- endog_df %>% dplyr::select(2:7 | 13) %>% VAR(., type = "const", season = 4,

8. 1.B: Tests on VAR

8.1. White Noise Residuals

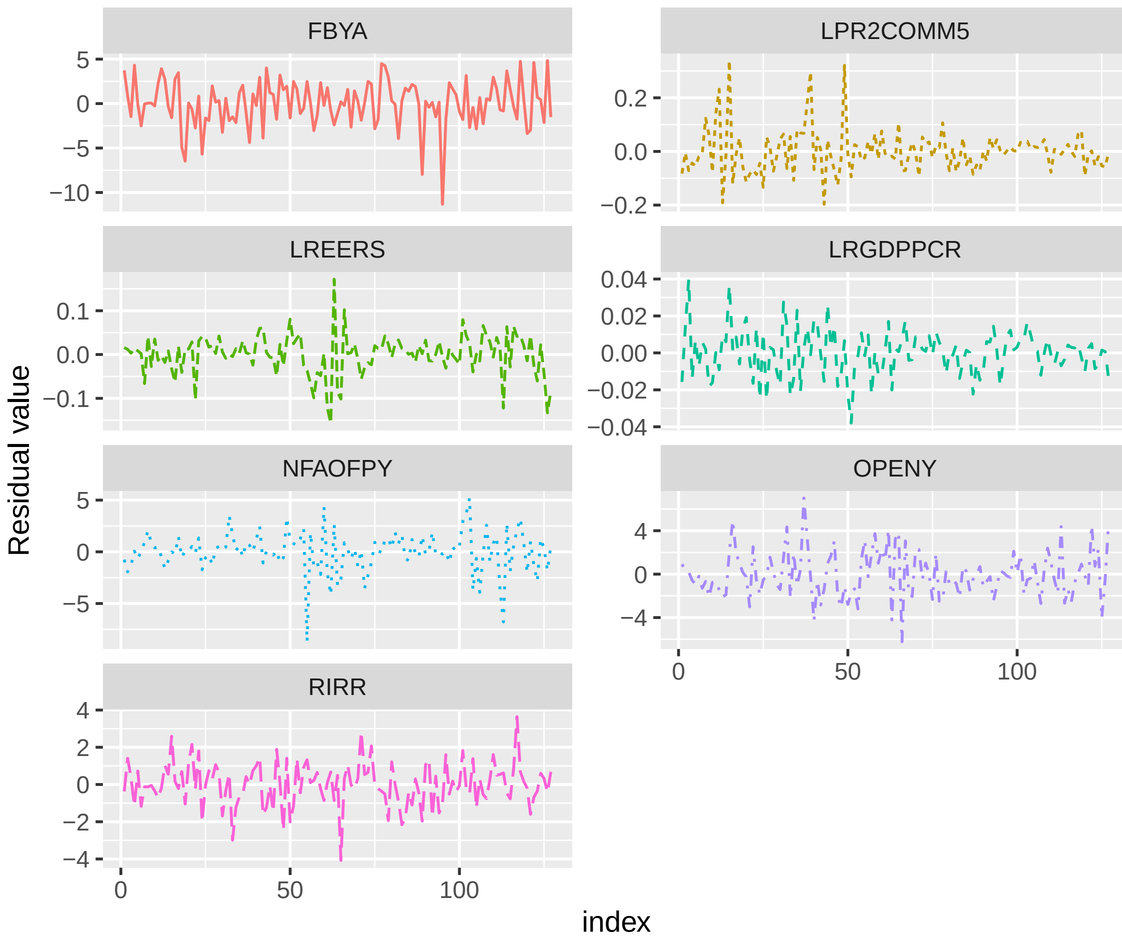

Figure 8.1: VAR Residuals plot - Model 1

The plot of the residuals from the first VAR model in figure 8.1 seems very close to a white noise process, however, there do appear to be deviations from the zero mean that could imply otherwise. The clusters of larger residuals appear to be concentrated around the timeline that corresponds with the outliers identified by MacDonald & Ricci (2004). Alternatively, this could add an additional illustration of the underlying effect of a structural change in the data.

```

11. Directly from (MacDonald & Ricci, 2004)

11.1. Section 3 Data and Methodology

- Plotting the exp(LREER) and the rest of the variables
- Showcase the vector of interest
- Investigate LR CI Rel's amongst var's in vector
  - Method: MLE of Johansen (1995)
  - Why? Corrects for Autocorr and ednog parametrically using VECM specif.
  - Key Advantage: the estimated coefficient - the β vector - can be used to provide a measure of the equilibrium real exchange rate and therefore a quantification of the gap between

the prevailing real exchange rate and its equilibrium level. The methodology also derives estimates of the speed at which the real exchange rates converges to the equilibrium level.
